Abstract

Background: Aggressive embryo and receptive endometrium are necessary for successful implantation. On this time endometrium transforms to receptive state, which permits embryonic implantation. Studies about embryonic implantation and endometrial receptivity are always a hot spot in the field of reproductive medicine.

Objective: To investigate the expression pattern of Meis1 during peri-implantation in mice endometrium.

Materials and Methods: Mice for experiment were raised in SPF environment. The mice were mated with a female/male ratio of 2:1. The female mice with detected plugs were regarded as pregnant day 1 (pd1). Endometrial tissues were collected respectively on pd1, pd2, pd4, pd5 and pd6. Immunohistochemistry was used to detect the location of Meis1 in mice endometrium. The expression level of mRNA and protein of Meis1 were further detected using Quantitative PCR and Western blotting, respectively.

Results: We found that Meis1 is located in the cytoplasm and membrane of endometrial glandular epithelium cells and the nucleus of endometrial stromal and decidual cells. Both Quantitative RT-PCR and western blotting showed that Meis1 expressed regularly in mice endometrium. Meis1 mRNA expressed weakly on pd1, then significantly increased on pd4 ($p=0.018$), and achieved to a peak on pd5 ($p=0.0012$), it showed a decrease trend on pd6. Meis1 protein expressed weakly on pd1 and pd2, then significantly increased on pd4 and pd5 ($p=0.0019$), it showed a decrease trend on pd6.

Conclusion: Meis1 is dynamically expressed in mice endometrium during peri-implantation. The time that Meis1 expression reaches its peak value is coincident with the implantation window, which implied that Meis1 is closely related with embryonic implantation.

Key words: Meis1, Embryonic implantation, Endometrial receptivity, Peri-implantation.

Introduction

Embryonic implantation is one of the key steps in mammal reproduction. There are many conditions that must be satisfied in order for a successful implantation to take place, once there is something wrong, it will most likely to be a miscarriage (1).

Homeobox genes (HOX) are a group of gene family that are involved in the regulation of morphogenesis, and are highly conservative among different species, including animals, fungi and plants. HOX regulates embryo development and cell differentiation through forming positive and negative regulation feedbacks with upstream signaling molecules and downstream target genes (2). It was reported that HOXA10 is involved in development of female genital

system; it has a key role to uterus development, endometrial proliferation and differentiation, as well as endometrial receptivity establishment (3).

HOX genes bind to regulatory DNA sequence of downstream target gene through coiling-turn-coiling motif so as to activate or inhibit the expression of downstream target genes and the capability of HOX genes to discriminate target genes is restrict (4). Meis1 (Myeloid ecotropic viral integration site) is a member of Three Amino Acid Loop Extension (TALE) family, which locates on 2p13-p14 of human chromosome and end of mouse chromosome11.

Hetero-dimers comprised of the HOX protein and Meis will greatly reinforce the affinity and specificity of HOX's ability to bind target sequence (5). For example, the Meis1-

HOXA10 hetero-dimer specifically identifies DNA sequence of TGACAGTTAT (4).

Receptive endometrium is necessary for successful implantation, and increasing studies have indicated that HOXA10 and Meis1 are intimately correlated with the establishment of endometrial receptivity (6). It was reported that Meis1 participates in the process of embryonic implantation as a co-factor of HOXA10 (7).

In this study, to investigate the association between Meis1 and endometrial receptivity, we detected the dynamic expression pattern of Meis1 in mice endometrium during peri-implantation.

Materials and methods

Animals

This is a descriptive study. The study was approved by the Animal Care and Use Committee (ACUC) of Guangzhou General Hospital of Guangzhou Military Region. Virgin six to eight-week-old specific pathogen free KM mice were supplied by Animals Experimental Center in Guangzhou General Hospital of Guangzhou Military Region. The mice were housed in 12/12h light/dark cycle at $25\pm0.5^{\circ}\text{C}$ and 50-60% humidity and were fed ad libitum with a standard pellet diet and water.

The mice were mated when they achieved to 18-20-week-old or 20-25g body weight. The mice were put together with a female/male ratio of 2:1 at 5.00 pm. the plugs were detected at 8.00 am. the next day. Once the plug appeared, it was regarded as pregnant day 1(pd1). All pregnant mice were divided into five groups according to their pregnant duration (pd1, pd2, pd4, pd5 and pd6), each group contains 10 mice.

Tissue collection

Endometrial tissue was collected routinely, endometrial biopsy were done at 9.00 am every day. The endometrial tissue was washed in frozen PBS. Half of the tissue sample was immediately frozen in nitrogen until the extraction of mRNA and protein. The other tissues were fixed in 10% formalin, embedded in paraffin, and then sectioned.

Immunohistochemistry

The expression of mouse Meis1 was evaluated by immunohistochemistry using a rabbit polyclonal antibody to Meis1 (ab19867, Abcam, USA). The above sections were deparaffinized in xylene and gradient ethanol. Endogenous peroxidase was blocked by 3% H_2O_2 at room temperature for 10 min. After blocking for 20 min with 1.5% normal goat serum in PBS, the sections were incubated overnight at 4°C with primary Meis1 antibody (1:100) in PBS.

The sections were then incubated with biotinylated goat anti-rabbit IgG (ZDR-5306, Zhongshan Goldenbridge Biotechnology co. LTD, CHINA) as a secondary antibody at 1:50 and incubated at 37°C for 20 min, then with DAB (400 mg/ml) at room temperature for 5 min, counterstained by haematoxylin, following dehydration, and clearing. Finally mounting was done for observation with microscope. Negative control was set for each group.

RNA isolation and Quantitative RT-PCR

Total RNA of each sample was extracted routinely using the total RNA isolation reagent (Invitrogen) according to the manufacturer's instructions. Reverse transcription was performed with the M-MLV Reverse Transcriptase (Promega) using $1\mu\text{l}$ of total RNA. The cDNA was sent for Quantitative PCR reactions, which were performed using the ABI 7700 system and the amplifications were done using the SYBR Green PCR Master Mix (Applied Biosystems). The primers for mouse Meis1 were: forward primer 5'-AAG CAG TTG GCA CAA GAT ACA GGA C-3', reverse primer 5'-TGA CTG CTC GGT TGG ACT GG-3', and for mouse β -actin: forward primer 5'-GAG ACC TTC AAC ACC CCA GCC-3', reverse primer 5'-TCG GGG CAT CGG AAC CGC TCA-3'.

The thermal cycling conditions were composed of 50°C for 2 min followed by an initial denaturation step at 95°C for 10 min, 30 cycles at 95°C for 40s, 50°C for 50s and 72°C for 60s. The experiments were carried out in duplicate for each data point. The relative quantification in gene expression was determined using the $2^{-\Delta\Delta\text{Ct}}$ method. Using this

method, we obtained the fold changes in gene expression normalized to β -actin.

Western blotting

Tissues from each mouse uterus were washed twice with PBS and lysed on ice in lysis buffer. Solid cellular debris was removed by centrifugation at 12,000 rpm for 5min. Protein concentration was measured by the BCA methods. The protein samples (50 μ g each) were subjected to 10% SDS-PAGE and transferred onto PVDF using a Bio-Rad electroblot apparatus (Bio-Rad). Non-specific binding sites were blocked in 5% (w/v) non-fat milk in TBS containing 0.05% (v/v) Tween-20. The primary antibody was added and incubated at 4°C overnight.

The dilutions for rabbit anti-Meis1 (Abcam) and rabbit anti-actin antibody (Santa Cruz) were 1:200 and 1:500, respectively. After washing by TBS, the secondary antibody goat peroxidase-conjugated anti-rabbit IgG (Zhongshan Goldenbridge Biotechnology) was used at a dilution of 1: 1000, and incubated at 37°C for 1h. After washing by TBS, protein bands were visualized by ECL (Pierce Biotechnology). Densitometric analysis of the film was performed using a Model GS-710 imaging densitometer (Bio-Rad Laboratories) in transmittance mode and analyzed using Bio-Rad Discovery software.

Statistical analysis

All numerical results are expressed as the mean \pm SD. The Meis1 expression in endometrium during peri-implantation were analyzed by analysis of variance. $P < 0.05$ was considered significant in all tests. The Statistical Package for the Social Sciences software package for Windows (Version 13.0) was used for all statistical analyses.

Results

Immunohistochemical localization of Meis1 during the implantation window of mice

Meis1 expressed in granular epithelial cells, endometrial stromal cells and decidual cells. With the elongation of pregnancy duration, the expression of Meis1 gradually increased. Different cell types showed different expression pattern. Granular epithelial cells showed a cytoplasm and membrane expression pattern while the endometrial stromal cells and decidual cells showed nucleus expression. It was weakly expressed both in granular epithelial cells and in endometrial stromal cells on pd1, then mildly increased on pd2, it significantly increased on pd4, especially in nucleus of endometrial stromal cells, and achieved a peak on pd5. In decidual tissue, Meis1 located in nucleus.

Expression of Meis1 mRNA during peri-implantation

Meis1 mRNA was expressed in mice endometrium during the peri-implantation, its expression levels were gradually increased, and achieved the peak on pd5, then decreased on pd6.

Expression of Meis1 protein during peri-implantation

The expression of endometrial Meis1 during peri-implantation was further confirmed by Western blotting (Figure 3). When normalized with β -actin expression levels, Meis1 protein was also significantly increased on pd4 ($p < 0.01$), and achieved the peak on pd5, then decreased on pd6.

Figure1. Immunohistochemical staining for the expression of endometrial Meis1 during peri-implantation.

A~E were the expression of Meis1 in the mouse endometrium of pregnant day 1, day 2, day 4, day 5 and day 6, respectively. Photomicrographs were taken at $\times 200$ magnification.

Discussion

Embryonic implantation is a complex biological process between maternal endometrium and embryo, which includes blastocystic localization, adhesion, invasion and endometrial decidualization, etc. (1, 8). The process of implantation involves a complicate succession of genetic and cellular interactions, all of which must be executed within an optimal time frame. The peri-implantation is started by preparations in the endometrium of the uterus, and the endometrium transforms to a receptive state. It was reported that Meis1 is intimately correlated with the establishment of endometrial receptivity (6, 7).

Therefore we investigate the expression pattern of Meis1 in mice endometrium during peri-implantation. We detected the expression of Meis1 during various time of peri-implantation in mice endometrium using different methods. Our data provides evidence that Meis1 is dynamically regulated during peri-implantation, which shows it involved in implantation. We found that the Meis1 expression gradually increased along with the pregnancy duration, and reached a peak on pd5, and then it decreased, which is coincident with the implantation window.

The TALE family of homeodomain proteins represents a most important group of HOX cofactors whom shares sequence homology outside of the homeobox domain. Single

TALE proteins have only low DNA-binding activity and specificity, however, the unique TALE motif within their homeodomain allows TALE proteins to interact with other homeobox-containing proteins.

Once combined with another subfamily of HOX-class homeobox protein, they show powerful and specific downstream target promoter regulation. *Meis1* was first identified as a major integration site for leukemogenic virus in a murine leukemia model, aberrant activation of *Meis1* is related to the genesis of human leukemia, and the defect of *Meis1* is intimately related to congenital heart disease as well (9, 10). Orlovsky *et al* stated that down-regulation of homeobox genes *Meis1* and *HOXA* in MLL-rearranged acute leukemia impairs engraftment and reduces proliferation (11).

HOXA10 is essential for normal embryonic uterine development. Benson *et al* induced altered *HOXA10* expression as a result of targeted mutation, which leads to abnormal uterine development (12). It was reported that the Hox cofactors *Meis1* and *Pbx* act upstream of *gata1* to regulate primitive hematopoiesis (13). *Pbx* and *Meis* cofactors are also involved in *HOXA10* target gene recognition in the endometrial cells, which suggests that these proteins may be essential for endometrial receptivity. The temporal and spatial expression patterns of *Meis1* and *Pbx2* as well as that of *HOXA10* indicated that HOX-*Pbx2* dimers in the glands and *HOXA10*-*Pbx2*-*Meis1* trimers in the stroma activate or repress downstream target gene expression. These transcription factor complexes likely regulate endometrial receptivity (14).

It was confirmed that HOX cofactors expression in normal human ovary is temporally and spatially specific and regulated by FSH and GDF-9 in granulosa cells (15). HOX proteins require co-operation with other proteins to bind the target DNA. *Meis1* in particular aids 5' HOX proteins, like *HOXA10*, to gain this specificity. *Meis1* physically interacts with 5' HOX proteins *HOXA9-11* by forming heterodimeric binding complexes on a DNA target containing a MEIS1 site (TGA CAG) and an Abd-B-like Hox site (TTT TAC GAC). Previous studies confirmed that *Meis1* gene and *HOXA9-13* genes are co-expressed throughout Müllerian duct differentiation, which suggests that *Meis1* plays an important role in embryonic female genital tract

development (16). The temporal and spatial expression pattern of *Meis1* and *HOXA10* indicate that *HOXA10*- *Meis1* dimers activate or repress downstream target gene expression.

Previous studies confirmed that the expression of *HOXA10* in endometrium is regulated by ovarian estrogen and progesterone. Both hormones can enhance the expression of *HOXA10*, and the effect of the latter is more obviously; The *HOXA10* expression in endometrial stromal cells is intensified by combination of estrogen and progesterone (17). It was confirmed that *Meis1* expressed both in endometrial stromal cells and in glandular epithelial cells, and it is expressed stronger in the latter.

The expression pattern of *Meis1* gene was investigated at different stages of human menstrual cycle, which demonstrated that *Meis1* is expressed in endometrium at different levels, depending on the menstrual cycle stage. *Meis1* mRNA level is significantly increased in mid-secretory phase, closely resembling the expression pattern of *HOXA10*. It implied that *Meis1* may be one of the regulating factors of endometrial receptivity formation in implantation period, and it was important for the process of embryo implantation mediated by *HOXA10* (7). The immunohistochemical research showed that *Meis1* was widely expressed in mouse uterine issue during the peri-implantation period, while different cells showed a different expression profile. *Meis1* was expressed in the cytoplasm and membrane of glandular epithelial cells, while in the nucleus of endometrial stromal cells and decidual cells.

Conclusion

Meis1 is dynamically expressed in mice endometrium during peri-implantation period. The time for *Meis1* expression to reach its peak value is coincident with the implantation window. Our study indicates that *Meis1* could be a potential molecular marker for endometrial receptivity.
