a graph *G* with *n* vertices, its Estrada index is defined as  $EE(G) = \sum_{i=1}^{n} e^{\lambda_i}$  with  $\lambda_2, ..., \lambda_n$  are the eigenvalues of *G*. A lot of properties especially lower and that sid For a graph *G* with *n* vertices, its Estrada index is defined as  $EE(G) = \sum_{i=1}^{n}$  $\sum_{i=1}^{n} e^{\lambda_i}$  where  $\lambda_1, \lambda_2, ..., \lambda_n$  are the eigenvalues of *G*. A lot of properties especially lower and upper bounds for the Estrada index are known. We now establish further lower bounds for the Estrada index.

**Keywords:** Estrada index, eigenvalues (of graph), spectral moments, lower bounds.

### **1 INTRODUCTION**

Let *G* be a simple graph with *n* vertices. Let  $\lambda_1, \lambda_2, ..., \lambda_n$  be the eigenvalues of *G* arranged in a non-increasing order [1]. The Estrada index of the graph *G* is defined as

$$
EE = EE(G) = \sum_{i=1}^{n} e^{\lambda_i}.
$$

This graph invariant was proposed as a structure-descriptor, used in the modeling of certain features of the 3D structure of organic molecules [2], in particular of the degree of proteins and other long-chains biopolymers [3,4]. It has also found applications in a large variety of other problems, see, e.g., [5−7]. Lower and upper bounds have been established for the Estrada index, see [8−14]. Some other properties for the Estrada index may be found in [15−19]. Here we present some easily computed lower bounds for the Estrada index.

#### **2 PRELIMINARIES**

Let G be a graph with *n* vertices. For  $k = 0, 1, 2, \dots$ , denote by  $M_k = M_k(G)$  the k-th spectral moment of the graph *G* , i.e., 1 .  $\sum_{k=1}^{n} k^k$  $k = \angle I$ <sup>n</sup>i *i*  $M_{\scriptscriptstyle k} = \sum \lambda_i^{\scriptscriptstyle \prime}$ =  $=\sum \lambda_i^k$ . Note that  $M_1 = 0$ . Then

$$
EE(G) = \sum_{i=1}^{n} \sum_{k \geq 0} \frac{\lambda_i^k}{k!} = \sum_{k \geq 0} \frac{M_k}{k!} = n + \sum_{k \geq 2} \frac{M_k}{k!}.
$$

*Archive 1201 Archive of vertex u* and  $V(G)$  is the vertex set of *G*. Let  $t(G) = \sum_{a \in V(G)} f(a)$  degree of vertex *u* and  $V(G)$  is the vertex set of *G*. Let  $t(G)$  be the in *G*. Recall that  $M_k$  is equal to the number of The first Zagreb index [20] of the graph G is defined as  $Zg(G) = \sum d_i^2$  $(G)$  $(G) = \sum d_u^2$ ,  $u \in V(G)$  $Zg(G) = \sum_{u \in V(G)} d_u^2$ , where  $d_u$  is the degree of vertex u and  $V(G)$  is the vertex set of G. Let  $t(G)$  be the number of triangles in G. Recall that  $M_k$  is equal to the number of closed walks of length k in the graph [1].

**Lemma 1.** Let G be a graph with m edges. Then for  $k \geq 4$ ,  $M_{k+2} \geq M_k$  with equality for all even  $k \geq 4$  if and only if G consists of m copies of complete graph on two vertices and possibly isolated vertices, and with equality for all odd  $k \geq 5$  if and only if G is a bipartite graph.

**Proof** (i) For even  $k \geq 4$ , by repeating the first edge twice for a closed walk of length *k*, we get a closed walk of length  $k+2$ , and then  $M_{k+2} \ge M_k$  with equality for all even  $k \geq 4$  if and only if G consists of m copies of complete graph on two vertices and possibly isolated vertices.

(ii) For odd  $k \ge 5$ , by similar considering as above, it is easily seen that  $M_{k+2} \ge M_k$ with equality for all odd  $k \geq 5$  if and only if G is bipartite. ■

# **3 RESULTS**

We now establish several lower bounds for the Estrada index and compare them with the known bounds in the literature.

**Proposition 2.** Let G be a graph with *n* vertices and *m* edges. Then

$$
EE(G) \ge n + m + t(G) + \frac{1}{2}(e + e^{-1} - 3)M_4 + \frac{1}{2}\left(e - e^{-1} - \frac{7}{3}\right)M_5
$$
\n(1)

$$
EE(G) \ge n + m + t(G) + (e + e^{-1} - 3)[Zg(G) - m] + 15\left(e - e^{-1} - \frac{7}{3}\right)t(G)
$$
 (2)

with either equality if and only if *G* consists of *m* copies of complete graph on two vertices and possibly isolated vertices.

**Proof.** Note that  $M_2 = 2m$ ,  $M_3 = 6t$  (G). By Lemma 1,

$$
EE(G) = n + m + t(G) + \sum_{k\geq 2} \frac{M_{2k}}{(2k)!} + \sum_{k\geq 2} \frac{M_{2k+1}}{(2k+1)!}
$$
  
\n
$$
\geq n + m + t(G) + \sum_{k\geq 2} \frac{M_4}{(2k)!} + \sum_{k\geq 2} \frac{M_5}{(2k+1)!}
$$
  
\n
$$
= n + m + t(G) + M_4 \left( \frac{e + e^{-1}}{2} - 1 - \frac{1}{2!} \right) + M_5 \left( \frac{e - e^{-1}}{2} - 1 - \frac{1}{3!} \right)
$$
  
\n
$$
= n + m + t(G) + \frac{1}{2} (e + e^{-1} - 3) M_4 + \frac{1}{2} \left( e - e^{-1} - \frac{7}{3} \right) M_5
$$
  
\nality if and only if  $M_k = M_4$  for all even  $k \geq 4$  and  $M_k = M_5$  for all  
\nLemma 1, is equivalent to the fact that G consists of m copies of com  
\nvertices and possibly isolated vertices.  
\nor a fixed vertex u, there are at least  $d_u^2$  closed walks of length four st  
\n $u(d_u - 1)$  closed walks of length four starting from a neighbor of u  
\nin such walks are only u and its neighbors, and then  $M_4 \geq 2Z$   
\n $M_4 = 2Zg(G) - 2m + 8q$  where q is the number of quadrangles in G  
\nthat  $M_5 \geq 30t(G)$  because there are ten closed walks of length five st  
\nertex on a fixed triangle such that the vertices of the walks are only the

with equality if and only if  $M_k = M_4$  for all even  $k \ge 4$  and  $M_k = M_5$  for all odd  $k \ge 5$ , which by Lemma 1, is equivalent to the fact that *G* consists of *m* copies of complete graph on two vertices and possibly isolated vertices.

For a fixed vertex  $u$ , there are at least  $d<sub>u</sub><sup>2</sup>$  closed walks of length four starting from *u* and  $d_u(d_u - 1)$  closed walks of length four starting from a neighbor of *u* such that vertices in such walks are only *u* and its neighbors, and then  $M_4 \geq 2Zg(G) - 2m$ . (Actually,  $M_4 = 2Zg(G) - 2m + 8q$  where *q* is the number of quadrangles in *G*, see [21]). Note also that  $M_s \geq 30 t(G)$  because there are ten closed walks of length five starting from a fixed vertex on a fixed triangle such that the vertices of the walks are only the vertices of the triangle. (Actually,  $M_5 = 30t(G) + 10p + 10r$  where p is the number of pentagons, and  $r$  is the number of subgraphs consisting of a triangle with a pendent vertex attached [21]. Now the second inequality follows. ■

**Corollary 3.** Let *G* be a graph with *n* vertices and *m* edges. Then

$$
EE(G) \ge n + m + (e + e^{-1} - 3)[Zg(G) - m]
$$
\n(3)

with equality if and only if G consists of m copies of complete graphs on two vertices and possibly isolated vertices.

Recently, Das and Lee [14] showed that for a connected graph with *n* vertices and  $m \geq 1.8n + 4$  edges,  $EE(G) > EE(P_n)$ . This may be improved slightly using Corollary 3. Recall that [14]  $EE(P_n) < 2.746n + 3.569$ . If  $m \ge 1.4n + 2$ , then by Corollary 3 and the Cauchy-Schwarz inequality, we have

$$
EE(G) \ge n + m + (e + e^{-1} - 3) \left( \frac{4m^2}{n} - m \right) > 2.746n + 3.569 > EE(P_n).
$$

**Remark 4.** For a graph *G* with  $n \ge 2$  vertices, it was shown in [12] that  $\frac{\lambda_1}{n}$ 

$$
EE(G) \ge e^{\lambda_1} + (n-1)e^{-\frac{\lambda_1}{n-1}}
$$
 (4)

with equality if and only if  $G$  is the empty graph or the complete graph. Obviously,  $(3)$ and (4) are incomparable.

**Remark 5.** Let G be a graph with *n* vertices, *m* edges and nullity (number of zero eigenvalues)  $n_0 < n$ . Note that  $n_0 = n$  if and only if G is an empty graph. Gutman [11] showed that

$$
EE(G) \ge n_0 + \frac{n - n_0}{2} (e^a + e^{-a})
$$
\n(5)

*EE(G)*  $\ge n + m + (e + e^{-1} - 3) \left( \frac{m}{n} - m \right) > 2.746n + 3.569 > E E(P_n)$ .<br> **4.** For a graph *G* with  $n \ge 2$  vertices, it was shown in [12] that<br> *EE(G)*  $\ge e^{\lambda_1} + (n-1)e^{-\frac{\lambda_1}{n-1}}$ <br>
ality if and only if *G* is the empty graph o with equality if and only if  $n - n_0$  is even, G consists of copies of complete bipartite graphs  $K_{r_j,t_j}$ ,  $j = 1, 2, \ldots, (n - n_0)/2$ , such that all  $r_j t_j$  are equal, and the remaining vertices if exist are isolated vertices, where  $a = \sqrt{2m/(n-n_0)}$ . A different proof may be found in [12]. For odd cycle  $C_n$  with  $n \ge 3$ ,  $n_0 = 0$  (see [21]) and  $m = n$ , we have

$$
n + m + (e + e^{-1} - 3)[Zg(G) - m] - \left[n_0 + \frac{n - n_0}{2} \left(e^a + e^{-a}\right)\right]
$$
  
=  $n \left[2 + 3(e + e^{-1} - 3) - \frac{e^{\sqrt{2}} + e^{-\sqrt{2}}}{2}\right] > 0.$ 

Then for odd cycle  $C_n$  with  $n \ge 3$ , the bound in (3) is better than the one in (5), and thus it is easily seen that (3) and (5) are incomparable in general.
