ABSTRACT. If M is a compact Riemannian manifold and  $C(M, R)$  is the set of all real valued continuous functions defined on  $M$ , then we show that for typical element  $f \in C(M, R)$ ,  $\overline{dim}_B(graph(f))$  is as big as possible and for typical  $f \in C(M, R)$ ,  $\dim_B(graph(f))$  is as small as possible.

Keywords: Manifold, Fractal, Box dimension.

2000 Mathematics subject classification: 54E50, 54E52, 54F45, 57N40.

# 1. INTRODUCTION

**Archive Constrainer Constrainer (Archive Constrainer SID**)<br> **Archive Constrainer Constrainer SID**<br> **ABBTRACT.** If *M* is a compact Riemannian manifold and  $C(M, R)$  is the<br>
set of all real valued continuous functions defin A subset  $A$  of a topological space  $X$  is called to be *comeagre*, if there is a countable collection  $\{W_i\}$  of open and dense subsets of X such that  $\bigcap_i W_i \subset A$ . Complement of a comeagre subset is called a meagre subset. A meagre subset can be considered as subset of a countable union of nowhere dense subsets and they are negligible in some sense. So, we say that some property holds for typical elements of  $X$ , if it holds on a comeagre subset. Study of properties of typical elements in  $X$  is a classic and interesting problem. One can find many papers dealing with typical elements when X is supposed to be the space  $C(W, R)$  of all continuous functions defined on a compact topological space  $W$ , endowed with the metric topology defined by the metric  $d(f, g) = \sup_{x \in W} |f(x) - g(x)|$ . A well known theorem due to Banach [1], states that typical elements of  $C([0, 1], R)$  are nowhere differentiable, so the image or graph of a typical f in  $C([0, 1], R)$  is a fractal set. Calculating fractal dimensions (including box dimension, Hausdorff

dimension, packing dimension, etc) of the image of f or  $graph(f)$  is a well known problem and one can find many results in the literature. It is proved in [6] that for a typical  $g \in C([0,1], R)$ ,  $dim_H(graph(g)) = 1$ . It is proved in [3] that if  $W \subset R$  is bounded with only finitely many isolated points and  $X = \{f \in C(W, R) : f \text{ is uniformly continuous }\},\$  then for a typical  $f \in$ X,  $\dim_B(\text{graph}(f))$  is as big as possible and  $\dim_B(\text{graph}(f))$  is as small as possible. In the previous paper [7] we generalized Banach's theorem to the set  $C(M, R)$ , where M is a compact Riemannian manifold. Now, we show in the present paper that the main results of [3] about upper and lower box dimensions are also true when  $W$  is replaced by a compact Riemannian manifold  $M$ .

#### 2. Preliminaries

In what follows, M is a compact Riemannian manifold with the Riemannian metric d, and  $C(M, R)$  will denote the collection of all continuous functions defined on M endowed with the metric d defined by  $d(f, g) = max_{x \in M} |f(x)$  $g(x)$ .

If  $(X, d_1)$  and  $(Y, d_2)$  are metric spaces then we will consider the usual product metric d on  $X \times Y$  defined by  $d((x_1, y_1), (x_2, y_2)) = \sqrt{d_1^2(x_1, x_2) + d_2^2(y_1, y_2)}$ .

If  $E$  is a bounded subset of  $M$  then the upper box dimension of  $E$  is defined by

$$
\overline{dim}_B(E) = lim \sum_{\delta \to 0} \frac{N_{\delta}(E)}{-log \delta}.
$$

present paper that the main results of [3] about upper and lower box dimensions<br>rec also true when *W* is replaced by a compact Riemannian manifold *M*,<br>2. PRELIMINARIES<br>In what follows, *M* is a compact Riemannian manifo Where,  $N_{\delta}(E)$  is the minimum number of balls of radius  $\delta$  ( or minimum number of sets of diameter at most  $\delta$ ) covering E (The lower box dimension  $\dim_B(E)$ is defined in similar way). Another definition for dimension, which is widely used in fractal geometry is Hausdorff dimension (see [4]).

Now, we mention some facts which we need in the proofs of theorems.

Remark 2.1. If E is a bounded subset of  $R^m$  then  $\overline{dim}_B(E\times I^n) = \overline{dim}_B(E)+n$ . The similar result is true if we replace  $\overline{dim}_B$  by  $\underline{dim}_B$  or  $dim_H$ .

*Proof.* We give the proof for  $\overline{dim}_B(E \times I) = \overline{dim}_B(E) + 1$ . The general case comes by induction. If  $\delta > 0$  then the smallest number of intervals of length  $\delta$ covering I is equal to  $[\frac{1}{\delta}]$  or  $[\frac{1}{\delta}]+1$ . If  $U_{\delta}(I_{\delta})$  is a bounded subset of  $R^m(I)$ Example 1 is equal to  $\left[\frac{1}{\delta}\right]$  or  $\left[\frac{1}{\delta}\right]$  + 1. If  $\mathcal{O}_{\delta}$  ( $I_{\delta}$ ) is a bounded subset with diameter  $\delta$ , then the diameter of  $U_{\delta} \times I_{\delta}$  is equal to  $\sqrt{2}\delta$ . So,

$$
N_{\sqrt{2}\delta}(E \times I) \le (\left[\frac{1}{\delta}\right] + 1)N_{\delta}(E)
$$

Then we have

$$
\overline{dim}_B(E \times I) = limsup_{\delta \to 0} \frac{log(N_{\sqrt{2}\delta}(E \times I))}{-log(\sqrt{2}\delta)}
$$

$$
\leq limsup_{\delta \to 0} \frac{log([\frac{1}{\delta}] + 1)N_{\delta}(E))}{-log(\sqrt{2}\delta)}
$$

$$
= 1 + limsup_{\delta \to 0} \frac{N_{\delta}(E)}{-log\delta} = 1 + \overline{dim}_B(E)
$$

Also we know that  $\overline{dim}_B(E \times I^n) \ge \overline{dim}_B(E) + n$  (see [4]). So we get the equality.

Remark 2.2. If M is a compact metric space and  $f : M \to R$  is a locally lipschitz function, then  $f$  is globally lipschitz.

*Proof.* Since  $f$  is locally lischitz and  $M$  is compact, then there is a finite collection of open cover of balls  $B_i, 1 \leq i \leq m$ , and constants  $L_i$  such that

$$
d(f(x), f(y)) \le L_i d(x, y), \quad x, y \in B_i
$$

Also we know that  $\overline{dim}_B(E \times I^n) \geq \overline{dim}_B(E) + n$  (see [4]). So we get the<br> *Remark* 2.2. If *M* is a compact metric space and  $f : M \rightarrow R$  is a locally<br> *Proof.* Since  $f$  is locally listiniz and *M* is compact, then there is Since M is compact then the function  $F : M \times M \to R$ , defined by  $F(x, y) =$  $d(f(x), f(y))$  has a maximum which we denote it by N. Let  $\delta$  be the lebesgue's number related to the covering  $B_i$  of M, and put  $L = max\{\frac{N}{\delta}, L_i : i\}$ . Then for given  $x, y \in M$ , either there is a  $B_i$  such that  $x, y \in B_i$  or  $d(x, y) \ge \delta$ . In the first case we have  $d(f(x), f(y)) \leq Ld(x, y)$ . In the second case we have

$$
d(f(x), f(y)) \le N \le \frac{N}{\delta}d(x, y) \le Ld(x, y)
$$

If M and N are compact differentiable manifolds and  $f : M \to N$  is continuously differentiable, then  $f$  is a lipschitz function. So, we get the following remark easily.

Remark 2.3. If M and N are compact Riemannian manifolds and  $\phi : M \to N$ is a map such that  $\phi$  and its inverse are continuously differentiable, then the map  $\psi$  :  $\overline{M} \times R \to N \times R$  defined by  $\psi(x, y) = (\phi(x), y)$  is bilipschitz.

Remark 2.4. If M is a compact Riemannian manifold,  $f : M \to R$  is continuously differentiable,  $g : M \to R$  is continuous and  $k = f + g$ , then  $\overline{dim}_B(graph(k)) = \overline{dim}_B(graph(g))$ . The same result is true for  $\underline{dim}_B$ .

*Proof.* Consider the map  $\psi$  :  $graph(g) \rightarrow graph(k)$ , defined by  $\psi(x, g(x)) =$  $(x, k(x))$ . We show that  $\psi$  and  $\psi^{-1}$  are Lipschitz functions. We have

$$
d(\psi(x,g(x)),\psi(y,g(y))) = d((x,k(x)),(y,k(y))) = \sqrt{d^2(x,y) + (k(x) - k(y))^2}
$$

*<www.SID.ir>*

96 R. Mirzaie

Since  $f$  is continuously differentiable, it is locally Lischitz and by Remark 2.2, it must be Lischitz. Then, there exist a positive number  $N$  such that  $|f(x) - f(y)| \leq N d(x, y), x, y \in M$ . Thus

$$
(k(x) - k(y))^2 = (f(x) - f(y) + g(x) - g(y))^2 \le (Nd(x, y) + |g(x) - g(y)|)^2
$$
  
=  $N^2d^2(x, y) + 2Nd(x, y)|g(x) - g(y)| + |g(x) - g(y)|^2$   

$$
\le N^2d^2(x, y) + N^2d^2(x, y) + |g(x) - g(y)|^2 + |g(x) - g(y)|^2
$$
  
=  $2N^2d^2(x, y) + 2|g(x) - g(y)|^2$ 

Then

Then  
\n
$$
d(\psi(x, g(x)), \psi(y, g(y))) \leq \sqrt{d^2(x, y) + 2N^2d^2(x, y) + 2|g(x) - g(y)|^2}
$$
\n≤√2(N<sup>2</sup> + 1)√d<sup>2</sup>(x, y) + (g(x) - g(y))<sup>2</sup> = √2(N<sup>2</sup> + 1) d((x, g(x)), (y, g(y))).  
\nTherefore,  $\psi$  is Lipschitz. In a similar way we can show that  $\psi^{-1}$  is Lipschitz.  
\nRemark 2.5. (generalized StoneWeierstrass Theorem). Suppose X is a com-  
\npart Hausdorff space and A is a subalgebra of C(X, R) which contains a non-  
\nzero constant function. Then A is dense in C(X, R) if and only if it separates  
\npoints.  
\n3. RESULTS  
\n**Lemma 3.1.** If  $f : M \rightarrow R$  is continuously differentiable and  $\epsilon > 0$ , then  
\nthere exists  $g \in C(M, R)$  such that  $d(f, g) < \epsilon$  and  $\overline{dim}_B(graph(g)) = n + 1$ ,  
\n $n = dimM$ .  
\nProof. Let N be a compact Riemannian manifold. Consider a function  $g_1 \in$   
\n $g_2 \cdot I^n = I \times I^{n-1} \rightarrow R^+$ ,  $g_2(t_1, t_2) = g_1(t_1)$ .  
\nThen  
\n $graph(g_2) = \{((t_1, t_2), g_1(t_1)), (t_1, t_2) \in I \times I^{n-1}\} \simeq$   
\n $\{( (t_1, g_1(t_1)), t_2), (t_1, t_2) \in I \times I^{n-1} \} = graph(g_1) \times I^{n-1}$ .  
\nSo, by Remark 2.1  
\n
$$
\overline{dim}_B(graph(g_2)) = 2 + n - 1 = n + 1.
$$

*Remark* 2.5. (generalized StoneWeierstrass Theorem). Suppose  $X$  is a compact Hausdorff space and A is a subalgebra of  $C(X, R)$  which contains a nonzero constant function. Then A is dense in  $C(X, R)$  if and only if it separates points.

### 3. RESULTS

**Lemma 3.1.** If  $f : M \to R$  is continuously differentiable and  $\epsilon > 0$ , then there exists  $g \in C(M, R)$  such that  $d(f, g) < \epsilon$  and  $\overline{dim}_B(graph(g)) = n + 1$ ,  $n = dim M$ .

*Proof.* Let N be a compact Riemannian manifold. Consider a function  $g_1 \in$  $C(I, R^+)$  such that  $\overline{dim}_B(graph(g_1)) = 2$  and put

$$
q_2: I^n = I \times I^{n-1} \to R^+, \quad q_2(t_1, t_2) = g_1(t_1).
$$

Then

$$
graph(g_2) = \{((t_1, t_2), g_1(t_1)), (t_1, t_2) \in I \times I^{n-1}\} \simeq
$$
  

$$
\{((t_1, g_1(t_1)), t_2), (t_1, t_2) \in I \times I^{n-1}\} = graph(g_1) \times I^{n-1}
$$

.

So, by Remark 2.1

 $\mathcal{L}$ 

$$
\overline{dim}_B(graph(g_2)) = 2 + n - 1 = n + 1.
$$

Consider a chart  $(U, \phi)$  on N such that  $I^n \subset \phi(U)$  and put  $W = \phi^{-1}(I^n)$ . Now, put  $g_3 = g_2 o \phi : W \to R$ . By Remark 2.3, the function  $\psi : W \times R \to I^n \times R$ , defined by  $\psi(x, y) = (\phi(x), y)$  is bilipschitz. Since  $\psi(graph(g_3)) = graph(g_2)$ , then  $\overline{dim}_B(graph(g_3)) = n+1$ . Extend the function  $g_3$  to a continuous function  $g_4: N \to R$ . Since  $graph(g_3) \subset graph(g_4)$  then  $\overline{dim}_B(graph(g_4)) = n+1$ . Now put  $N = graph(f)$ . We know that N is a submanifold of  $M \times R$ , which with the induced metric is a riemannian manifold. Given  $\delta > 0$ , the function  $g_5 = \delta g_4$ :  $N \to R$  is a positive function such that  $\overline{dim}(graph(g_5)) = \overline{dim}(graph(g_4))$ 

*<www.SID.ir>*

 $n + 1$ . By compactness condition we can choose  $\delta$  small enough such that for all  $y = (x, f(x)) \in N$ ,  $g_5(y) < \epsilon$ .

Now, consider the function  $g_6: M \to R$ , defined by  $g_6(x) = g_5(x, f(x))$  and put  $\psi : M \times R \to N \times R$ ,  $\psi(x, y) = ((x, f(x)), y)$ . We have

$$
\psi : graph(g_6) = graph(g_5)
$$

By Remark 2.3,  $\psi$  is bilipshitze, so

 $\overline{dim}_B(graph(q_6)) = \overline{dim}_B(graph(q_5)) = n+1$ 

Put  $g: M \to R$ ,  $g(x) = f(x) + g_6(x)$ . Since f is differentiable, then by Remark 2.4,  $\overline{dim}_B(graph(g)) = \overline{dim}_B(graph(g_6) = n + 1$ . Also, we have  $d(f, g)$  $max_{x \in M} |g(x) - f(x)| = max_{x \in M} |g_6(x)| = max_{x \in M} g_5(x, f(x)) < \epsilon.$ 

**Theorem 3.2.** Let M be a compact Riemannian manifold,  $dim(M) = n$ , and  $C(M, R)$  be the set of all continuous functions defined on M. Then for typical members f in  $C(M, R)$ ,  $\underline{dim}_B(graph(f)) = n$ .

Proof. Put

$$
A=\{f\in C(M,R): \underline{dim}_B(graph(f))=n\}.
$$

Let  $f \in A$  and consider a positive number  $\epsilon > 0$  and  $g \in C(M, R)$  such that  $d(f,g) < \epsilon$ . If a collection of balls of radius  $\delta$  in  $M \times R$  covers graph(f) and  $\epsilon < \delta$ , then the same number of balls with radius 2δ covers graph(g). Since each ball of radius  $2\delta$  can be covered by  $4^{n+1}$  balls of radius  $\delta,$  then

$$
N_{\delta}(graph(g)) \leq 4^{n+1}N_{\delta}(graph(f))
$$

If  $\delta < 1$  then

$$
\frac{log N_{\delta}(graph(g))}{-log(\delta)} \leq (n+1)\frac{lo4}{-log\delta} + \frac{log N_{\delta}(graph(f))}{-log\delta}
$$

Since  $\underline{dim}_B(graph(f)) = n$  and  $\lim_{\delta \to 0} \frac{\log 4}{-\log \delta} = 0$ , then for each  $k \in N$  there exists  $\delta = \delta(f, k) > 0$  such that

Put 
$$
g: M \to R
$$
,  $g(x) = f(x) + g_6(x)$ . Since  $f$  is differentiable, then by Remark  
\n2.4,  $\overline{dim}_B(graph(g)) = \overline{dim}_B(graph(g_6) = n + 1)$ . Also, we have  $d(f, g) =$   
\n $max_{x \in M} |g(x) - f(x)| = max_{x \in M} |g_6(x)| = max_{x \in M} g_5(x, f(x)) < \epsilon$ .  
\n**Theorem 3.2.** Let  $M$  be a compact Riemannian manifold,  $dim(M) = n$ , and  
\n $C(M, R)$  be the set of all continuous functions defined on  $M$ . Then for typical  
\nmembers  $f$  in  $C(M, R)$ ,  $\underline{dim}_B(graph(f)) = n$ .  
\nProof. Put  
\n $A = \{f \in C(M, R) : \underline{dim}_B(graph(f)) = n\}$ .  
\nLet  $f \in A$  and consider a positive number  $\epsilon > 0$  and  $g \in C(M, R)$  such that  
\n $d(f, g) < \epsilon$ . If a collection of balls with radius  $\delta$  in  $M \times R$  covers graph $(f)$  and  
\n $\epsilon < \delta$ , then the same number of balls with radius  $2\delta$  covers graph $(g)$ . Since  
\neach ball of radius  $2\delta$  can be covered by  $4^{n+1}$  balls of radius  $\delta$ , then  
\n $N_{\delta}(graph(g)) \leq 4^{n+1}N_{\delta}(graph(f))$   
\nIf  $\delta < 1$  then  
\n $\frac{logN_{\delta}(graph(g))}{log(\delta)} \leq (n+1)\frac{log}{-log\delta} + \frac{logN_{\delta}(graph(f))}{-log\delta}$   
\nSince  $\underline{dim}_B(graph(f)) = n$  and  $\lim_{\delta \to 0} \frac{\log_4}{-\log\delta} = 0$ , then for each  $k \in N$  there  
\nexists  $\delta = \delta(f, k) > 0$  such that  
\n $\log N_{\delta}(graph(g)) \leq (n+1)\frac{\log_4}{-\log\delta} + \frac{\log N_{\delta}(graph(f))}{-\log\delta} < n + \frac{1}{k}$   
\nPut  
\n $U_{f,k} = \$ 

and

 $\mathbf P$ 

$$
W_k = \bigcup_{(f \in A)} U_{f,k}
$$

 $W_{f,k}$  is an open set in  $C(M, R)$  such that for each  $g \in W_k$ ,

$$
\underline{\dim}_B(\operatorname{graph}(g) < n + \frac{1}{k}.
$$

Clearly  $A \subset \bigcap_k W_k$ . If  $g \in \bigcap_k W_k$  then  $\underline{\dim}_B(\text{graph}(g)) \leq n$ , and since for all  $g \in C(M, R)$ ,  $n \leq \underline{dim}_B(graph(g))$  then  $\underline{dim}_B(graph(g)) = n$ . Thus

*<www.SID.ir>*

98 R. Mirzaie

 $\bigcap_k W_k = A$ . Now, we show that  $W_k$  is dense for all k, then the proof will be complete. Given  $g \in C(M, R)$  and  $\epsilon > 0$ . By Remark 2.5, collection of differentiable functions is dense, so there exists a differentiable function  $f: M \to R$  such that  $d(f,g) < \epsilon$ . But for a differentiable function f,  $\underline{dim}_B(graph(f)) = \overline{dim}_B(graph(f)) = n.$  So  $f \in A \subset W_k$ .

**Lemma 3.3.** If  $g \in C(M, R)$  and  $\epsilon > 0$ , then there exists  $k \in C(M, R)$  such that  $d(g, k) < \epsilon$  and  $\overline{dim}_B(graph(k)) = n + 1$ .

*Proof.* By Remark 2.5, for a given  $\delta > 0$  there exists a differentiable function  $f \in C(M, R)$  such that  $df, g) < \delta$ . Consider a function  $f_1 \in C(M, R)$  such  $\delta$  and  $f_2 \in C(M, R)$  such that  $|\delta_1 f_1(x)| < \delta_2$  for all  $x \in H + \delta_1 f$ *Proof.* By Remark 2.5, for a given  $\delta > 0$  there exists a differentiable function  $f \in C(M, R)$  such that  $d(f, g) < \delta$ . Consider a function  $f_1 \in C(M, R)$  such that  $\overline{dim}_B(graph(f_1)) = n+1$ . Since M is compact, for a given number  $\delta_2 > 0$ there is a positive number  $\delta_1$  such that  $|\delta_1 f_1(x)| < \delta_2$  for all  $x \in M$ . Now, put  $k = f + \delta_1 f_1$ . By Remark 2.4, we have

$$
\overline{dim}_B(gradph(k) = \overline{dim}_B(gradph(\delta_1 f_1)) = \overline{dim}_B(gradph(f_1)) = n + 1.
$$

If we choose  $\delta$  and  $\delta_2$  smaller than  $\frac{\epsilon}{2}$ , then

$$
d(g,k) \leq d(g,f) + d(f,k) \leq \delta + \delta_1 ||f_1|| \leq \delta + \delta_2 < \epsilon.
$$

 $\Box$ 

**Theorem 3.4.** Let M be a compact Riemannian manifold,  $dim(M) = n$ , and  $C(M, R)$  be the set of all continuous functions defined on M. Then for typical members f in  $C(M, R)$ ,  $\overline{dim}_B(graph(f)) = n + 1$ .

*Proof.* Clearly for all 
$$
f \in C(M, R)
$$
,  $\overline{dim}_B(graph(f)) \leq n + 1$ . Put

$$
A = \{ f \in C(M, R) : dim_B(graph(f)) = n + 1 \}.
$$

Consider  $f \in A$ , a positive number  $\epsilon > 0$  and  $g \in C(M, R)$  such that  $d(f, g) < \epsilon$ . If a collection of balls of radius  $\delta$  in  $M \times R$  covers  $graph(g)$  and  $\epsilon < \delta$ , then the same number of balls with radius  $2\delta$  covers  $graph(f)$ . Since each ball of radius  $2\delta$  can be covered by  $4^{n+1}$  balls of radius  $\delta$ , then

$$
N_{\delta}(graph(f)) < 4^{n+1}N_{\delta}(graph(g))
$$

So, if  $\delta < 1$  then  $logN_{\delta}(graph(f))$  $\frac{I_{\delta}(graph(f))}{-log(\delta)} < (n+1)\frac{lo4}{-log\delta} + \frac{logN_{\delta}(graph(g))}{-log\delta}$  $-log\delta$ 

Since  $\overline{dim}_B(graph(f)) = n+1$ , then for each  $k \in N$  there is  $\delta(k) = \delta(f, k) >$ 0 such that

$$
n+1-\frac{1}{k}<\frac{logN_{\delta(k)}(graph(f))}{-log(\delta(k))}-(n+1)\frac{log4}{-log\delta(k)}<\frac{logN_{\delta(k)}(graph(g))}{-log\delta(k)}
$$

Put

$$
U_{f,k} = \{ g \in C(M, R) : d(f, g) < \delta(f, k) \}
$$

and

$$
W_k = \bigcup_{(f \in A)} U_{f,k}
$$

 $W_k$  is an open set in  $C(M, R)$  such that for each  $g \in W_k$ ,

$$
\overline{dim}_B(graph(g) > n + 1 - \frac{1}{k}
$$

Clearly

$$
\bigcap_k W_k = A
$$

 $\left[\begin{array}{l} W_k = A \end{array}\right] W_k = A$ <br>Sow it remains to show that  $W_k$  is dense for all  $k$ . Let  $h \in C(M, R)$  and  $\epsilon > 0$ <br> *As*, the collection of all differentiable functions is dense in  $C(M, R)$  such that  $d(h, g) < \epsilon$ . Since by Remark<br> Now it remains to show that  $W_k$  is dense for all k. Let  $h \in C(M, R)$  and  $\epsilon > 0$ we show that there exists  $g \in W_k$  such that  $d(h, g) < \epsilon$ . Since by Remark 2.5, the collection of all differentiable functions is dense in  $C(M, R)$  then there exists a differentiable function  $g_1 \in C(M, R)$  such that  $d(h, g_1) < \frac{\epsilon}{2}$ . Consider a function  $f \in A \subset W_k$ . Since f is continuous and M is compact then there exists  $\delta > 0$  such that  $|\delta f(x)| < \frac{\epsilon}{2}$  for all  $x \in M$ . Now, put  $g = g_1 + \delta f$ . Since  $g_1$ is differentiable then  $\overline{dim}_B(graph(g) = \overline{dim}_B(graph\delta f) = \overline{dim}_B(graph(f)) =$  $n + 1$ . So,  $g \in A \subset W_k$  and we have

$$
d(h,g) \le d(h,g_1) + d(g_1,g) \le \frac{\epsilon}{2} + \max_{x \in M} |\delta f| < \frac{\epsilon}{2} + \frac{\epsilon}{2} = \epsilon
$$
