A KIND OF F-INVERSE SPLIT MODULES

M. HOSSEINPOUR AND A. R. MONIRI HAMZEKOLAEE*

Abstract. Let M be a right module over a ring R. In this manuscript, we shall study on a special case of F-inverse split modules where F is a fully invariant submodule of M introduced in [12]. We say M is $\overline{Z}^2(M)$-inverse split provided $f^{-1}(\overline{Z}^2(M))$ is a direct summand of M for each endomorphism f of M. We prove that M is $\overline{Z}^2(M)$-inverse split if and only if M is a direct sum of $\overline{Z}^2(M)$ and a $\overline{Z}^2$-torsionfree Rickart submodule. It is shown under some assumptions that the class of right perfect rings R for which every right R-module M is $\overline{Z}^2(M)$-inverse split ($\overline{Z}(M)$-inverse split) is precisely that of right GV-rings.

1. Introduction

Throughout this paper R denotes a ring with identity, modules are unital right R-modules and $S = End_R(M)$ denotes the ring of all right R-module endomorphisms of a module M unless otherwise stated. Also $N \leq M$ states that N is a submodule of a module M.

The notions of Rickart and Baer rings have their roots in functional analysis with close links to C^*-algebras and von Neumann algebras. Kaplansky introduced the notion of Baer rings in 1955 [4] which was extended to quasi-Baer rings in 1967 [1]. A ring R is called *(quasi-)Baer* if the right annihilator of any nonempty subset (two-sided ideal) of R is generated by an idempotent as a right ideal. Closely related to the concept of Baer rings is the more general notion of right Rickart

rings. The concept of right (left) Rickart rings has been comprehensively studied in the literature. A ring R is called *right Rickart* if the right annihilator of any single element of R is generated by an idempotent of R as a right ideal. Let R be a ring, M be a right R-module and $S = End_R(M)$. Following [5], M is a *Rickart* module if the right annihilator in M of any single element of S is generated by an idempotent of S, equivalently, $r_M(f) = Kerf$ is a direct summand of M for every $f \in S$. It is easy to see that for $M = R_R$, the notion of a Rickart module coincides with that of a right Rickart ring. Hence R_R is a Rickart module if R is a Baer ring, a von Neumann regular ring or a right hereditary ring (see [5]). In [5], the authors investigated Rickart modules and their properties and study the connections between a Rickart module and its endomorphism ring.

A submodule N of a module M is said to be *small* in M if $N+K \neq M$ for any proper submodule K of M. Also a module L is said to be a *small module*, in case L is a small submodule of a module T. Following [2], a module M is called *lifting* if every submodule $N \leq M$ there exists a direct summand D of M such that $N/D \ll M/D$. A submodule N of M is called a *supplement* in M if there is a submodule K of M such that $M = N+K$ and $N \cap K \ll N$. A module M is called *supplemented* if every submodule of M has a supplement in M. A module M is *amply supplemented* if $M = A + B$, then A contains a supplement of B in M. A lifting module is amply supplemented and hence supplemented. Let R be a ring and M a right R-module. In [10], Talebi and Vanaja defined $\overline{Z}(M)$ as a dual of singular submodule as follows: $\overline{Z}(M) = \cap\{Kerf \mid f : M \to U, U \in \mathcal{S}\}$ (here $\mathcal{S}$ denotes the class of all small right R-modules). They called M a *cosingular (noncosingular)* module if $\overline{Z}(M) = 0$ ($\overline{Z}(M) = M$). Clearly every small module is cosingular. In [10], $\overline{Z}^{\alpha}(M)$ is defined by $\overline{Z}^{0}(M) = M$, $\overline{Z}^{\alpha+1}(M) = \overline{Z}(\overline{Z}^{\alpha}(M))$ and $\overline{Z}^{\alpha}(M) = \bigcap_{\beta<\alpha} \overline{Z}^{\beta}(M)$ if α is a limit ordinal. Hence there is a descending chain $M = \overline{Z}^{0}(M) \supseteq \overline{Z}(M) \supseteq \overline{Z}^{2}(M) \supseteq \dots$ of submodules of M.

Recall that a submodule F of a module M is called *fully invariant* if $h(F) \subseteq F$ for every $h \in End_R(M)$. Let F be a fully invariant submodule of a module M. Then M is said to be F-*inverse split* [12], if $h^{-1}(F)$ is a direct summand of M for every $h \in End_R(M)$. In [13], the authors defined $\overline{Z}(M)$-inverse split modules and investigated their properties. A module M is $\overline{Z}(M)$-*inverse split* provided $h^{-1}(\overline{Z}(M))$ is a direct summand of M for each endomorphism h of M. They proved that a module M is $\overline{Z}(M)$-inverse split if and only if M is decomposed to a noncosingular submodule and a cosingular Rickart submodule if and only if $M = \overline{Z}(M) \oplus N$ where N is cosingular Rickart. In this article, we define $\overline{Z}^2(M)$-inverse split modules and try to investigate their general properties. We say M is $\overline{Z}^2(M)$-inverse split provided $h^{-1}(\overline{Z}^2(M))$ is a direct summand of M for each endomorphism h of M. We prove that a module M is $\overline{Z}^2(M)$-inverse split if and only if M is decomposed to $\overline{Z}^2(M)$ and a $\overline{Z}^2$-torsion free Rickart submodule N. We also present, under some assumptions, new characterizations of right perfect right GV-rings in terms of $\overline{Z}^2$-inverse split modules.

2. $\overline{Z}^2$-inverse split modules

In this section, we are interested in studying on a special case of F-inverse split modules. There are many important fully invariant submodules of a module. Among all of them, the second cosingular submodule of a module M, namely $\overline{Z}^2(M)$, has a key role in determining of some important modules such as lifting modules and amply supplemented modules.

We start with introducing $\overline{Z}^2$-inverse split modules.

Definition 2.1. A module M is called $\overline{Z}^2(M)$-inverse split whenever $f^{-1}(\overline{Z}^2(M))$ is a direct summand of M for every $f \in S$.

Here are examples of some known $\overline{Z}^2$-inverse split modules.

Example 2.2. (1) The class of $\overline{Z}^2$-inverse split modules contains a large class of modules namely semisimple modules. In particular, every Artinian (Noetherian) module M over a Boolean ring R is $\overline{Z}^2(M)$-inverse split.

(2) It is clear that, every noncosingular module M is $\overline{Z}^2(M)$-inverse split. So that, every right R-module M over a right V-ring R, is $\overline{Z}^2(M)$-inverse split.

(3) Every injective right R-module M over a right hereditary ring is noncosingular (see [10, Proposition 2.7]) and hence is $\overline{Z}^2(M)$-inverse split.

(4) For a cosingular module M, two concepts "Rickart" and "$\overline{Z}^2(M)$-inverse split" coincide. Since a projective $\mathbb{Z}$-module has the form $M = \mathbb{Z}^{(I)}$ where I is an arbitrary nonempty index set, M is cosingular. From [5, Theorem 2.26], M is Rickart. So that M is $\overline{Z}^2(M)$-inverse split.

We exhibit a characterization of $\overline{Z}^2(M)$-inverse split modules which will be applied excessively throughout the paper.

Theorem 2.3. *Let M be a module. Then the following statements are equivalent:*

(1) *M is $\overline{Z}^2(M)$-inverse split;*

(2) *$M = \overline{Z}^2(M) \oplus N$ where N is a Rickart module with $\overline{Z}^2(N) = 0$;*

(3) *$M = K \oplus L$ where K is noncosingular and L is a Rickart module with $\overline{Z}^2(L) = 0$.*

Proof. (1) $\Rightarrow$ (2) Let M be $\overline{Z}^2(M)$-inverse split. So, $id_M^{-1}(\overline{Z}^2(M)) = \overline{Z}^2(M)$ is a direct summand of M. Set $M = \overline{Z}^2(M) \oplus N$ for $N \leq M$. We shall prove N is Rickart. To verify this assertion, suppose $g \in End(N)$. Then $f = jogo\pi_N$ is an endomorphism of M where $\pi_N : M \to N$ is the projection of M on N and $j : N \to M$ is the inclusion. Now, being M a $\overline{Z}^2(M)$-inverse split module leads us that $f^{-1}(\overline{Z}^2(M))$ is a direct summand of M. By a normal verification, we conclude that $f^{-1}(\overline{Z}^2(M)) = Kerg \oplus \overline{Z}^2(M)$. Hence $Kerg$ is a direct summand of M. As $Kerg$ is contained in N, we have $Kerg$ is a direct summand of N, showing N is Rickart.

(2) $\Rightarrow$ (1) Let $M = \overline{Z}^2(M) \oplus N$ where N is Rickart. Let $f \in End(M)$. Consider $h = \pi_N ofoj : N \to N$ which is an endomorphism of N such that $\pi_N : M \to N$ is the projection of M on N and $j : N \to M$ is the inclusion. Being N a Rickart module implies $Kerh$ is a direct summand of N. Set $Kerh \oplus L = N$. It is not hard to check that $f^{-1}(\overline{Z}^2(M)) = Kerh \oplus \overline{Z}^2(M)$. By the decomposition $M = (Kerh \oplus L) \oplus \overline{Z}^2(M)$ we come to a conclusion that $f^{-1}(\overline{Z}^2(M))$ is a direct summand.

(2) $\Rightarrow$ (3) Suppose that $M = \overline{Z}^2(M) \oplus N$. Then $\overline{Z}^4(M) = \overline{Z}^3(M) = \overline{Z}^2(M)$ showing that $\overline{Z}^2(M)$ is noncosingular.

(3) $\Rightarrow$ (2) If $M = K \oplus L$ where K is noncosingular and L is Rickart with $\overline{Z}^2(L) = 0$ then it is obvious that $K = \overline{Z}^2(M)$. □

The following is an immediate consequence of Theorem 2.3.

Corollary 2.4. *Every $\overline{Z}(M)$-inverse split module M is $\overline{Z}^2(M)$-inverse split.*

Example 2.5. Every Rickart module M with $\overline{Z}^2(M)$ a direct summand of M, is a $\overline{Z}^2(M)$-inverse split module. Let now M be a lifting Rickart module. Then by [10, Theorem 4.1], there is a decomposition $M = \overline{Z}^2(M) \oplus N$. It follows that M is $\overline{Z}^2(M)$-inverse split. In particular, every nonsingular injective (extending) lifting module M is $\overline{Z}^2(M)$-inverse split by [5, Example 2.3].

Definition 2.6. Let M be a module. We call M a $\overline{Z}^2$*-torsionfree* module provided $\overline{Z}^2(M) = 0$.

It is easy to see that every cosingular module is $\overline{Z}^2$-torsionfree. The class of $\overline{Z}^2$-torsionfree modules is closed under submodules, direct sums and direct products (see [10, Proposition 2.1]). It is also followed by [6, Theorem 4.41] and [10, Proposition 2.1 and Theorem 3.5] that for a perfect ring R, the class of $\overline{Z}^2$-torsionfree R-modules is also closed under factor modules.

Recall that a module M satisfies (D_0) in case $M = M_1 \oplus M_2$ implies M_1 and M_2 are relatively projective. We present a new characterization of right GV-rings in terms of $\overline{Z}^2$-inverse split modules.

We should note that the proofs for equivalences of (1), (2) and (3) of the following can be found distinctly in [8]. We state them here to make useful connections with $\overline{Z}^2$-inverse split modules.

Before presenting next result, it is worth to recall that a ring R is a right GV-ring (generalized V-ring) provided every simple singular right R-module is injective. In [8], some characterizations of right GV-rings are given. Among them, it is proved that a ring R is right GV if and only if every simple cosingular right R-module is projective if and only if every small right R-module is projective ([8, Theorem 3.1 and Corollary 3.3]).

Theorem 2.7. *Consider the following statements for a right perfect ring R:*

(1) *R is a right GV-ring;*

(2) *Every $\overline{Z}^2$-torsionfree right R-module is projective;*

(3) *Every right R-module is a direct sum of a noncosingular right R-module and a semisimple right R-module;*

(4) *Every right R-module M is $\overline{Z}^2(M)$-inverse split.*

Then (1) $\Leftrightarrow$ (2) $\Leftrightarrow$ (3) $\Rightarrow$ (4). *They are equivalent in case every $\overline{Z}^2$-torsionfree module satisfies (D_0).*

Proof. (1) $\Rightarrow$ (2) Assume that R is right GV. Let $0 \neq M$ be a $\overline{Z}^2$-torsionfree R-module, $0 \neq x \in M$ and K a maximal submodule of xR. Now the simple R-module xR/K is either singular or projective (but not both). If xR/K is singular, then it will be noncosingular by [7, Theorem 4.1]. Consider the natural epimorphism $\pi \colon xR \to xR/K$. Since R is a right perfect ring, by [6, Theorem 4.41] xR is amply supplemented. Therefore by [10, Theorem 3.5] we conclude that $0 = \pi(\overline{Z}^2(xR)) = \overline{Z}^2(xR/K) = \overline{Z}(xR/K) = xR/K$, which is a contradiction. Then xR/K is projective and so K is a direct summand of xR. Hence xR and as well as xR, the module M is semisimple. Let $M = \oplus_{i\in I} M_i$ where each M_i is simple. By mentioned argument in above, each M_i is projective. Hence M is projective.

(2) $\Rightarrow$ (3) Let M be a right R-module. Since R is a right perfect ring, M is amply supplemented by [6, Theorem 4.41]. Now consider natural epimorphism $\pi : M \to M/\overline{Z}^2(M)$. Hence by [10, Theorem 3.5], we have $0 = \pi(\overline{Z}^2(M)) = \overline{Z}^2(M/\overline{Z}^2(M))$. Now, we conclude by assumption that $\overline{Z}^2(M)$ is a direct summand of M. Suppose $M = \overline{Z}^2(M) \oplus N$ for a submodule N of M. It is clear that $\overline{Z}^2(M)$ is noncosingular. We shall show that N is semisimple. To verify this assertion, let $0 \neq x \in N$. As xR is finitely generated, it contains a maximal submodule say K. Consider the simple module xR/K which must be small or injective, but not both. Assume that xR/K is injective. Then xR/K is noncosingular. Now, designate the natural epimorphism $\pi : xR \to xR/K$. Being R a right perfect ring combining with [10, Theorem 3.5] implies that $0 = \pi(\overline{Z}^2(xR)) = \overline{Z}^2(xR/K) = \overline{Z}(xR/K) = xR/K$ which causes a contradiction. By the way, xR/K is small and therefore by assumption xR/K is projective concluding that K is a direct summand of xR. Hence xR is semisimple which implies N is semisimple.

(3) $\Rightarrow$ (1) Let M be a simple singular right R-module. Then M is either small or injective. If M is small, then it is projective which is a contradiction. It follows that M is injective.

(3) $\Rightarrow$ (4) Let M be a right R-module. By (3), there is a decomposition $M = N \oplus S$ where N is noncosingular and S is semisimple. Let us consider S as $(\oplus_{\alpha\in A}(S_\alpha)) \oplus (\oplus_{\beta\in B}(S'_\beta))$ while for each $\alpha \in A$, S_α is noncosingular and S'_β for each $\beta \in B$ is small (note that a simple module is either injective (noncosingular) or small). Now, $M = [N \oplus (\oplus_{\alpha\in A}(S_\alpha))] \oplus [(\oplus_{\beta\in B}(S'_\beta))]$ is a direct sum of $\overline{Z}^2(M)$ and a semisimple (Rickart) module. Hence, M is $\overline{Z}^2(M)$-inverse split by Theorem 2.3.

Now let every $\overline{Z}^2$-torsionfree module satisfy (D_0).

(4) $\Rightarrow$ (3) Let M be a module. Then by assumption, $M = \overline{Z}^2(M) \oplus N$ where N is a Rickart module. We shall prove that N is semisimple. To verify this assertion, take an arbitrary nonzero x in N. Being xR finitely generated implies xR has at least a maximal submodule. Suppose K is a maximal submodule of xR. As $\overline{Z}^2(xR \oplus xR/K) = 0$, it satisfies (D_0) by assumption (note that $\overline{Z}^2(xR/K) = (\overline{Z}^2(xR) + K)/K = 0$ as R is right perfect). It follows that xR/K is xR-projective which

implies that K is a direct summand of xR. Therefore, xR and hence N are semisimple.

□

Theorem 2.7 combining characterizations of GV-rings in [8], gives us the following:

Corollary 2.8. *Let R be a right perfect ring. Consider the following:*
(1) *R is a right GV-ring;*
(2) *Every (simple) cosingular right R-module is projective;*
(3) *Every right R-module is a direct sum of a noncosingular right R-module and a semisimple right R-module;*
(4) *Every right R-module M is $\overline{Z}^2(M)$-inverse split.*
Then (1) ⇔ (2) ⇔ (3) ⇒ (4). They are equivalent in case every $\overline{Z}^2$-torsionfree module satisfies (D_0).

Proof. It follows from Theorem 2.7, [8, Theorems 3.1 and 3.18]. □

We shall prove under some assumptions that the class of right perfect rings R for which every right R-module M is $\overline{Z}(M)$-inverse split is precisely that of right GV-rings.

Corollary 2.9. *Let R be a right perfect ring such that every $\overline{Z}^2$-torsionfree module satisfies (D_0). Then the following statements are equivalent:*
(1) *R is a right GV-ring;*
(2) *Every right R-module M is $\overline{Z}(M)$-inverse split;*
(3) *Every right R-module M is $\overline{Z}^2(M)$-inverse split.*

Proof. (1) ⇒ (2) Let M be a right R-module. It follows from Corollary 2.8 that $M = N \oplus S$ where N is noncosingular and S is semisimple. Similar to argument mentioned in (3) ⇒ (4) of the proof of Theorem 2.7, we can conclude that $M = \overline{Z}(M) \oplus H$ where H is semisimple. Hence by [13, Theorem 3.3], M is $\overline{Z}(M)$-inverse split.
(2) ⇒ (3) It is obvious.
(3) ⇒ (1) It follows from Theorem 2.7. □

Corollary 2.10. *Let R be a right perfect ring such that every noncosingular submodule of a module is a direct summand of that module. If every $\overline{Z}^2$-torsionfree right R-module satisfies (D_0), then every right R-module M is $\overline{Z}^2(M)$-inverse split.*

Proof. Let M be an arbitrary right R-module. By assumption $\overline{Z}^2(M)$ is a direct summand of M. Set $M = \overline{Z}^2(M) \oplus L$ for some submodule L of

M. It is clear that $\overline{Z}^2(L) = 0$, so that by assumption L satisfies (D_0). By a similar argument stated in (4) $\Rightarrow$ (3) of the proof of Theorem 2.7, L is semisimple. Therefore, M is $\overline{Z}^2(M)$-inverse split by Theorem 2.3. □

Corollary 2.11. *Let R be a left and right Artinian serial ring with $J(R)^2 = 0$. If every injective module is noncosingular, then every left and right R-module M is $\overline{Z}^2(M)$-inverse split. In particular, over a hereditary left and right Artinian serial ring R with $J(R)^2 = 0$, every R-module M is $\overline{Z}^2(M)$-inverse split.*

Proof. By [2, 29.10], every R-module M has a decomposition $M = E \oplus S$ where E is an injective R-module and S is a semisimple R-module. Now, by assumption E is noncosingular. The result follows from Theorem 2.7. The last assertion follows from first part and [10, Proposition 2.7]. □

The following introduces a ring over which every module M is $\overline{Z}^2(M)$-inverse split.

Example 2.12. ([8, Example 3.15]) Let F be a field and $R = \begin{bmatrix} F & F \\ 0 & F \end{bmatrix}$ the ring of 2×2 upper triangular matrices over F. By [3, Example 13.6], every singular (left and right) R-module is injective. Hence R is a left and right GV-ring. Since $J(R) = \begin{bmatrix} 0 & F \\ 0 & 0 \end{bmatrix}$, R can not be a (left and right) V-ring. Also R is (left and right) hereditary Artinian serial from [3, Example 13.6]. It is easy to check that $J(R)^2 = 0$. Hence by Corollary 2.11, every right R-module M is $\overline{Z}^2(M)$-inverse split.

There are $\overline{Z}^2(M)$-inverse split modules which are not Rickart. Now, consider the $\mathbb{Z}$-module $M = \mathbb{Z}_{p^\infty}^{(I)}$ for an arbitrary non-empty indexed set I. Then M is not Rickart, since $\mathbb{Z}_{p^\infty}$ is not a Rickart $\mathbb{Z}$-module by [5, Example 2.17]. On the other hand, M is noncosingular and so it is $\overline{Z}^2(M)$-inverse split. Generally, every non-Rickart noncosingular module provides an example of a $\overline{Z}^2(M)$-inverse split module that is not Rickart.

Proposition 2.13. *Let M be an indecomposable module. Then the following are equivalent:*

(1) *M is $\overline{Z}^2(M)$-inverse split;*

(2) *M is noncosingular or M is Rickart with $\overline{Z}^2(M) = 0$.*

Proof. (1) $\Rightarrow$ (2) Let M be $\overline{Z}^2(M)$-inverse split. Then by Theorem 2.3, $M = \overline{Z}^2(M) \oplus N$ where N is Rickart. Being M indecomposable implies $M = \overline{Z}^2(M)$ or $M = N$. First case yields M is noncosingular and the second one implies M is Rickart with $\overline{Z}^2(M) = 0$.

(2) $\Rightarrow$ (1) It is straightforward. □

Example 2.14. Consider the $\mathbb{Z}$-module $M = \mathbb{Z}_{p^n}$ where p is a prime and $n \in \mathbb{N}$. Then M is an indecomposable cosingular $\mathbb{Z}$-module. Now, earmark the endomorphism $h : M \to M$ by $h(x) = px$. It is clear that $0 \neq Kerh < M$. Therefore, M is not a Rickart $\mathbb{Z}$-module. As M is cosingular indecomposable, M is not $\overline{Z}^2(M)$-inverse split by Proposition 2.13.

Recall from [9] that a module M has C^**-property* provided that every submodule N of M contains a direct summand D of M such that N/D is cosingular. Let R be a ring. Then every right R-module satisfies C^* if and only if every right R-module is a direct sum of an injective module and a cosingular module (see [9, Theorem 2.9]). Recall also from [2] that a ring R is right Harada in case every injective right R-module is lifting. It follows from [2, 28.10] that R is right Harada if and only if every right R-module is decomposed to an injective right R-module and a small right R-module. So, over a right Harada ring every right R-module satisfies C^*.

Proposition 2.15. *Let R be a right perfect ring such that every right R-module has C^*-property. Then every Rickart R-module M is $\overline{Z}^2(M)$-inverse split. In particular, every Rickart module M over a Harada ring (quasi-Frobenius ring) is $\overline{Z}^2(M)$-inverse split.*

Proof. Let M be a Rickart module. As R is right perfect, $\overline{Z}^2(M)$ is a noncosingular submodule of M. Now, from [9, Theorem 2.9], there is a decomposition $\overline{Z}^2(M) = E \oplus C$ such that E is injective and C is cosingular. It follows that $\overline{Z}^2(M)$ is injective and hence a direct summand of M. Being M a Rickart module implies that M is $\overline{Z}^2(M)$-inverse split. □

The following contains an example of a $\overline{Z}^2(M)$-inverse split module which is not $\overline{Z}(M)$-inverse split showing that the concept of $\overline{Z}^2(M)$-inverse split modules is a proper generalization of the $\overline{Z}(M)$-inverse split modules.

Example 2.16. Let K be a field and

$$R = \left\{ \begin{pmatrix} a & 0 & 0 & 0 \\ 0 & a & b & 0 \\ 0 & 0 & c & 0 \\ d & 0 & 0 & c \end{pmatrix} \mid a, b, c, d \in K \right\}.$$

Then R is a subring of $M_{4\times 4}(K)$. Now consider $e = e_{11} + e_{22}$ and $f = e_{33} + e_{44}$ where e_{ij} is an element of R such that (i, j)-component is 1 and elsewhere is 0. Then e and f are two idempotents in R and $R = eR \oplus fR$. The ring R is a (4-dimensional) Frobenius algebra and eR is an indecomposable projective module where $Soc(eR) = e_{23}R$ is the only non-trivial proper submodule of eR (it can be easily checked). Therefore, eR is a local right R-module with $Soc(eR) = Rad(eR) \ll eR$. Now by [11, Corollary 2.8], we have $\overline{Z}(eR) = Soc(eR) \ll eR$, so that $\overline{Z}^2(eR) = 0$. Note that the only proper submodule of eR is $Soc(eR)$. Now, suppose that $\varphi : eR \to eR$ is an arbitrary nonzero endomorphism of eR. Then $Ker\varphi = 0$ or $Ker\varphi = Soc(eR)$. Since $eR/Soc(eR)$ is not isomorphic to a submodule of eR, we conclude that $Ker\varphi = 0$. In fact, $eR/Soc(eR)$ is isomorphic to a submodule of fR. Hence, $Ker\varphi$ is a direct summand of eR implying that eR is a Rickart right R-module. Now by Theorem 2.3, eR is $\overline{Z}^2(eR)$-inverse split while eR is not $\overline{Z}(eR)$-inverse split as $\overline{Z}(eR) \ll eR$.

A submodule N of a $\overline{Z}^2(M)$-inverse split module M need not be $\overline{Z}^2(N)$-inverse split. Now, consider the $\mathbb{Z}$-module $M = \mathbb{Q} \oplus \mathbb{Z}_2$. By Theorem 2.3 and [5, Example 2.5], M is $\overline{Z}^2(M)$-inverse split. Set $N = \mathbb{Z} \oplus \mathbb{Z}_2$ which is a cosingular submodule of M. By [5, Example 2.5], N is a Rickart $\mathbb{Z}$-module. Hence N is not a $\overline{Z}^2(N)$-inverse split module. We next show that a direct summand of a $\overline{Z}^2$-inverse split module inherits the property.

Proposition 2.17. *Let M be a $\overline{Z}^2(M)$-inverse split module and N a direct summand of M. Then N is $\overline{Z}^2(N)$-inverse split.*

Proof. Let $M = N \oplus K$ be a $\overline{Z}^2(M)$-inverse split module with N and K submodules of M. By Theorem 2.3, there is a decomposition $M = \overline{Z}^2(M) \oplus L$ where L is Rickart. Since $\overline{Z}^2(M) = \overline{Z}^2(N) \oplus \overline{Z}^2(K)$, we conclude that $M = \overline{Z}^2(N) \oplus \overline{Z}^2(K) \oplus L$. Modular law implies $N = \overline{Z}^2(N) \oplus [(\overline{Z}^2(K) \oplus L) \cap N]$. Let $Y = (\overline{Z}^2(K) \oplus L) \cap N$ and $f \in End_R(Y)$. It just remains to prove that Y is a Rickart module. It is easy to check that $h = jof o\pi_Y$ is an endomorphism of M where

$j : Y \to M$ is the inclusion map and $\pi_Y : M \to Y$ is the projection of M on Y. Being M a $\overline{Z}^2(M)$-inverse split module conduces that $h^{-1}(\overline{Z}^2(M)) = \overline{Z}^2(N) \oplus \overline{Z}^2(K) \oplus Kerf$ is a direct summand of M. By modular law, $Kerf$ is a direct summand of Y resulting that Y is a Rickart module. □

Theorem 2.18. *The following are equivalent for a module M:*

(1) *M is $\overline{Z}^2(M)$-inverse split and $Kerf$ is a direct summand of $f^{-1}(\overline{Z}^2(M))$ for any $f \in S$;*

(2) *M is Rickart and $\overline{Z}^2(M)$ is a direct summand of M.*

Proof. (1) $\Rightarrow$ (2) Let M be a $\overline{Z}^2(M)$-inverse split module and $f \in S$. Then $f^{-1}(\overline{Z}^2(M))$ is a direct summand of M and by hypothesis, $Kerf$ is a direct summand of $f^{-1}(\overline{Z}^2(M))$. It follows that M is Rickart. In addition, by Theorem 2.3, $\overline{Z}^2(M)$ is a direct summand of M.

(2) $\Rightarrow$ (1) Let M be a Rickart module and $M = \overline{Z}^2(M) \oplus N$ for some submodule N of M. Then N is Rickart and so M is $\overline{Z}^2(M)$-inverse split by Theorem 2.3. Being M Rickart leads us that $Kerf$ is a direct summand of M. The result follows from the fact that $Kerf$ is a submodule of $f^{-1}(\overline{Z}^2(M))$ for any $f \in S$. □

We shall state an analogue of [13, Theorem 3.12] for a $\overline{Z}^2(M)$-inverse split module.

Proposition 2.19. *Let $f : M \to M'$ be an epimorphism of modules where M is $\overline{Z}^2(M)$-inverse split. If $Kerf$ is noncosingular, then M' is $\overline{Z}^2(M')$-inverse split.*

Proof. Let M be $\overline{Z}^2(M)$-inverse split. Then by Theorem 2.3, $M = \overline{Z}^2(M) \oplus N$ where N is a Rickart module. It is easy to check that $\overline{Z}^2(N) = 0$. Taking image of M, we have $M' = f(\overline{Z}^2(M)) + f(N)$. As $Kerf$ is noncosingular, it is contained in $\overline{Z}^2(M)$. So by a similar argument given in the proof of [13, Theorem 3.12], we conclude that $M' = f(\overline{Z}^2(M)) \oplus f(N)$. Note that the condition $Kerf \subseteq \overline{Z}^2(M)$ implies there is an isomorphism between N and $f(N)$. Existing such isomorphism implies $f(N)$ is a Rickart module and $\overline{Z}^2(f(N)) = 0$, as well as $\overline{Z}^2(N) = 0$. Hence $M' = \overline{Z}^2(M') \oplus f(N)$. The result then follows from Theorem 2.3. □

A KIND OF F-INVERSE SPLIT MODULES

M. HOSSEINPOUR AND A. R. MONIRI HAMZEKOLAEE

یک نوع از مدول‌های Fـ وارون شکافته‌شدنی

محراب حسین‌پور و علیرضا منیری حمزه‌کلایی

فرض کنید M یک Rـ مدول راست روی حلقه R باشد. در این مقاله یک حالت خاص از مدول‌های Fـ وارون شکافته‌شدنی که در آن F یک زیرمدول کاملاً پایا از M است را مورد مطالعه قرار می‌دهیم. گوییم M یک مدول $\overline{Z}^{2}(M)$ـ وارون شکافته‌شدنی است هرگاه برای هر درونریختی f از مدول M، زیرمدول $f^{-1}(\overline{Z}^{2}(M))$ یک جمعوند مستقیم از M باشد. نشان دادیم M یک مدول $\overline{Z}^{2}(M)$ـ وارون شکافته‌شدنی است اگر و تنها اگر M مجموع مستقیم $\overline{Z}^{2}(M)$ و یک زیرمدول $\overline{Z}^{2}$ـ بدون تاب باشد. همچنین تحت شرایطی ثابت کردیم که حلقه‌ای که هر مدول مانند M روی آن $\overline{Z}^{2}(M)$ـ وارون شکافته‌شدنی باشد، دقیقاً یک Vـ حلقه‌ی تعمیم‌یافته است.

کلمات کلیدی: مدول ریکارت، مدول $\overline{Z}(M)$ـ وارون شکافته‌شدنی، مدول $\overline{Z}^{2}(M)$ـ وارون شکافته‌شدنی.
