We reported the first case of inoperative thymic adenocarcinoma successfully palliative treated by the double-stent procedure. In a patient who expressed stridor, computed tomography was done and necrotic mediastinal mass, which protrudes into a trachea, was demonstrated. Fiberoptic bronchoscopy showed tracheal infiltration and 70% stenosis; therefore, surgical resection was inapplicable. Recanalization with repeated argon plasma coagulation and debridement of necrotic mass was performed, followed by placement of the endotracheal stent, radiotherapy, and chemotherapy. After 1 year, the patient developed gastric aspiration and tracheoesophageal fistula; therefore, the esophageal stent was placed. The outcome was lethal, but the placement of endotracheal stent significantly increased a length of survival for the patient with invasive thymic adenocarcinoma.

Key words: Adenocarcinoma, palliative care, stent, thymus, tracheoesophageal fistula

INTRODUCTION

Primary thymic adenocarcinoma is extraordinarily rare with high malignant potential and poor prognosis.^[1] The multimodal approach in the treatment of thymic carcinomas includes surgery, radiotherapy, and chemotherapy.^[1] We report the case of inoperative thymic adenocarcinoma palliative successfully treated by the double stent.

CASE REPORT

A 53-year-old male developed a cough and stridor, 1 month after cholecystectomy. Spirometry results were within referent range, postintubation stenosis was suspected, and chest X-ray was done. Incidental 6.5 cm mediastinal mass was revealed [Figure 1a]. Computed tomography (CT) revealed enlarged subcarinal lymph nodes and necrotic mass (6.5 cm) protrudes into distal trachea and compression of

vena cava inferior (VCI) [Figure 1b]. Fiberoptic bronchoscopy showed 2 cm infiltration of the trachea with two-third stenosis. Needle biopsy showed branching papillae with fibrovascular cores composed of cells with nuclear atypia. Immunohistochemistry of necrotic tissue showed positivity for EA, CK-5/6/7/19, CD-5/117, CD-5, galectin-3, and carcinoembryonic antigen, what confirmed the diagnosis of thymic papillary adenocarcinoma [Figure 1c]. Other primary origin sites were excluded from the study. The tumor was inoperative due to the severity of symptoms and comprehensive tracheal stenosis. Recanalization with plasma coagulation, debridement of necrotic masses, and the placement of Polyflex endotracheal stent (Boston Scientific Co, Boston, Massachusetts, USA) [Figure 1d] was performed, followed by radiotherapy and chemotherapy (carboplatin 5 mg/ml and paclitaxel 225 mg/m²). General patient's condition was better, but 1 year later he developed a productive cough with foul-smelling sputum. Evaluation of sputum sample revealed gastric

Figure 1: (a) Initial chest X-ray revealed large mediastinal mass of 7 cm indicating a thymic carcinoma; (b) initial chest computed tomography scan demonstrates large mediastinal mass protruding into trachea; (c) direct microscopic examination revealed irregular nuclei consistent with thymic papillary adenocarcinoma confirmed by positive immunostaining for cytokeratin-19, (1) H and E, $\times 20$, (2) cytokeratin-19, $\times 40$ and (d) subsequent chest computed tomography following palliative placement of endotracheal stent

Figure 2: Visualization of the double stent of the trachea and esophagus with thorax computed tomography scan

content, while radioscopy with barium passage and thoracic CT revealed tracheoesophageal fistula. Therefore, 12 cm tracheoesophageal stent was placed to cover fistula [Figure 2]. One month later, right-side pneumothorax developed. Esophagogastroduodenoscopy and bronchoscopy revealed broncho-esophageal-pleural communication, with esophageal stent protruded into the trachea and right bronchus and with tracheal stent protrudes into the esophagus. Although thoracic drainage was performed, the patient died 4 days later.

DISCUSSION

This is the first case present thymic adenocarcinoma successfully treated with surgery and stent placement, afterward complicated with tracheoesophageal fistula.

Thymic adenocarcinoma is extraordinarily rare neoplasm with only a few case reports in the literature.^[1-3] Standard therapy regimens for thymic carcinomas include surgery, radiotherapy, and chemotherapy.^[4] There are only two reports in the literature based on radiotherapy alone with poor outcomes.^[5,6] In the presented case, surgery was not considered due to the extraluminal and intraluminal invasive tracheal propagation, VCI compression, and enlarged lymph nodes. Up to the best of our knowledge, this is the first case of stent placement in the patient with thymic adenocarcinoma aimed to improve patient's respiration, followed by radiotherapy and chemotherapy. Airway and/or esophageal stent insertion provides an effective approach to improve the quality of life in patients with malignant disease.^[7] Although rare, the double-stent procedure was reported in the case of esophageal carcinoma with tracheoesophageal fistula as the complication of chemotherapy and radiotherapy.^[8] In our patient, dyspnea reduced after esophageal stent placement.

Tracheobronchial and esophageal stent insertion are recommended for patients with thoracic malignancies with tracheoesophageal fistula with almost none reported complications of perforation.^[9] In patients with malignant tracheobronchial communication treated with supportive care alone, lethal outcome occurs rapidly with the mean survival time of 1–6 weeks.^[10] Stent placement should be considered as palliative care in patients with thymic carcinoma as it could extend survival.

Declaration of patient consent

The authors certify that they have obtained all appropriate patient consent forms. In the form the patient(s) has/have
