Editor, the recent article on “Toxocara canis IgG seropositivity in patients with chronic urticaria (CU)” is very interesting.¹ Burak-Selek et al. reported that “*T. canis* may trigger CU since we found 17.8% seropositivity in 73 patients with CU and none in 109 healthy individuals.”¹ In fact, *T. canis* is an uncommon parasitic infestation. In tropical countries, the patients can present with dermatological problems due to this parasite. In a recent case series report, skin problem can be seen in 43 % of the patients.² In animal model, the induction of eosinophilia due to this parasite can be observed.³ It is no doubt that it is presently approved that *T. canis* infection is an etiological factor of CU.⁴ The other possible dermatological problems due to *T. canis* infection include chronic pruritus, and miscellaneous eczema.⁴ Also Jeske et al. noted that “large joints lesions and augmentation in lymph nodes” were common problem seen in the patients with skin allergy as a result of *T. canis* infections.⁵ Since *T. canis* infection is a curable disease, the immunological evidences for this infection is suggested in the cases with unexplained CU.

Keywords: Toxocara; Urticaria
