C-C bond cleavage of aziridines

Heshmat Allah Samimi*, Mohsen Derakhshan

Department of Chemistry, Faculty of Sciences, Shahrekord University, P. O. Box 115, Shahrekord, Iran, E-samimi-h@sci.sku.ac.ir.

Aziridines exhibited intriguing and diverse reactivity, and thus have became unique and versatile synthons in organic synthesis. C–N/C-C bond cleavage of aziridine ring is a useful way to serve as three-atom synthons with extensive applications in organic synthesis. ¹

In contrast with ordinary solvents, such as Volatile Organic Compounds (<u>VOC</u>), DESs have a very low vapour pressure, and thus are non-flammable. The same reference mentions that DESs have a relatively high viscosities which might hinder their industrial applications as they might not flow easily in the process streams. DESs favorably possess low densities and can be liquid at a wide range of temperatures. Other studied properties for some DESs are their electrical conductivities, pH indices and surface tensions, which might be added to this article by any contributor.³

Unexpected regioselective oxidation of ketoaziridines to the corresponding aldehydes with choline chloride/thiourea is described. This regio-selective reaction presumably precedes via a domino sequence C-C/C-N cleavage of ketoaziridine ring. This metal-free method proved to be efficient for the oxidative cleavage of several ketoaziridines in moderate to good yields.

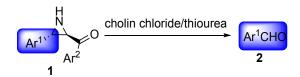

Figure 1. Regio-selective oxidation reaction of ketoaziridines
